System and Method for Verifying Database Security
Across Multiple Platforms

ABSTRACT

   A system and method for verifying database security
5 across multiple platforms is presented.   Servers are
queried to obtain a user id access list of a particular
database, directory, or file. The user id access list is
compared with a validated access list. A report file is
generated that includes user id's that have access to a
10 database, directory, or file but do not have proper
permission. The report file includes a submission of how
to correct each security violation.
